

You can modify a byte array directly because it is a mutable data type, whereas a bytes object is immutable. When Python creates a byte object, it allocates a fixed, read-only block of memory that cannot be changed after creation to ensure data integrity and allow it to be used as a dictionary key. In contrast, a bytearray allocates a dynamic memory buffer that permits elements to be overwritten or modified in-place without forcing Python to copy the entire object into a new memory location.
